# ImagesToLARModel, a tool for creation of three-dimensional models from a stack of images

Danilo Salvati

December 1, 2015

#### Abstract

Here we will present a software for creating a three-dimensional model from a stack of images. This can be useful because of the simplicity of these type of representations. In particular a scope of use can be offered by medicine, where there is an enormous number of images but with very complex two-dimensional representations.

This work will use the LAR representation ([CL13]) with the Julia language, because of its simplicity, showing how it can be used for quickly process image data.

#### 1 Introduction

This work has the aim to transform a two-dimensional representation of a model (based on a stack of images) into a three-dimensional representation based on the LAR schema. In particular, it will produce a single obj model which can be viewed with standard graphics softwares.

In the past were developed other softwares using same principles (see [PDFJ15]). However, they were optimized for speed and cannot be able to accept huge amounts of data. With the rise of the big data era, we now have more and more data available for research purposes, so softwares must be able to deal with them. A typical hardware environment is based on a cluster of computers where computation can be distributed among a lot of different processes. However, as stated by Amdahl's law, the speedup of a program using multiple processors is limited by the time needed for the sequential fraction of the program. So use of parallel techniques for dealing with big data is not important for time performance gain but for memory space gain. In fact, our biggest problem is lack of memory, due to model sizes. As a consequence, every parts of this software is written with the clear objective of minimizing memory usage at the cost of losing something in terms of time performance. So, for example, images will be converted in blocks determined by a grid size (see section 5) among different processes and different machines of the cluster

Figure 1: Amdahl's law

#### 1.1 Why Julia

Ricordare che precedenti versioni erano in python Semplicita Efficienza Capacita di realizzare programmi paralleli con poco sforzo

#### 2 Software structure

#### 2.1 Julia packages

This software will be distributed as a Julia Package. For the actual release (Julia 0.4) a package is a simple git project with the structure showed in figure 2

Figure 2: Julia module structure

Source code must be in folder src, while in test folder there are module tests with a runtests.jl for executing them and with a REQUIRE file for specifying tests dependencies. For listing dependencies for the entire project, there is another REQUIRE file in main folder. As an example in figure 3 there is the REQUIRE file for ImagesToLARModel.jl.

After creating this structure for a project it can be pushed on a git repository and installed on Julia systems. The usual installation procedure use this syntax:

#### Pkg.add("Package-name")

This will check for that package in METADATA.jl repository on github where there are all official Julia package. However it is also possible to install an unofficial package (on a public git repository) using this sintax:

julia 0.3 JSON Logging PyCall Images Colors Clustering

Figure 3: REQUIRE contents for ImagesToLARModel.jl

Pkg.clone("git://repository-address.git")

This will install the package on your system with all the dependencies listed in RE-QUIRE file.

#### 2.2 Architecture of ImagesToLARModel

In previous section we have seen how to create a Julia package for distribute our application. Now we focus on the structure of our application. In **src** folder we can find the following modules:

ImagesToLARModel.jl: main module for the software, it takes input parameters and start images conversion

ImagesConversion.jl: it is called by ImagesToLARModel.jl module and controls the entire conversion process calling all other modules

GenerateBorderMatrix.jl: it generates the boundary operator for grid specified in input, saving it in a JSON file

PngStack2Array3dJulia.jl: it is responsible of images loading and conversion into computable data

Lar2Julia.jl: it contains a small subset of LAR functions written in Julia language

LARUtils.jl: it contains utility functions for manipulation of LAR models

Smoother.jl: it contains function for smoothing of LAR models

Model2Obj.jl: it contains function that manipulates obj files

larcc.py: python larcc module for boundary computation. In next releases of the software it will be rewritten in Julia language

Figure 4: Schema of module dependencies of ImagesToLARModel

In figure 4 there is a simple schema of dependencies between modules.

Next sections of this document will explain in details all these modules showing also the code involved in conversion

## 3 Images To LAR Model

This is the main module for the application; it takes the input data and start conversion calling ImagesConversion.jl.

#### 3.1 Calling modules

As we have already said, this first module has the responsibility of starting the conversion calling all other modules in the package. In Julia calling modules requires that they are in a path specified by LOAD\_PATH array. So at the beginning of this module we need to add this line:

Fragment referenced in 72a.

Pkg.dir() function gives us the path of the Julia installation, so Pkg.dir("ImagesToLARModel/src") returns " $\langle Julia-path \rangle/ImagesToLARModel/src$ "

After this line we can now import all modules defined here and export public functions:

```
\langle \ modules \ import \ ImagesToLARModel \ 7 \rangle \equiv \\ import \ JSON \\ import \ ImagesConversion \\ using \ Logging \\ export \ convertImagesToLARModel
```

Fragment referenced in 72a.

#### 3.2 Input loading

Images conversion takes several parameters:

- inputDirectory: The path of the directory containing the stack of images
- outputDirectory: The path of the directory containing the output
- bestImage: Image chosen for centroid computation (see section 4)
- nx, ny, nz: Sizes of the grid chosen for image segmentation (see section 4)
- DEBUG\_LEVEL: Debug level for Julia logger
- parallelMerge (experimental): Choose between sequential or parallel merge of files (see section 10)

Because of their number it has been realized a function for simply loading them from a JSON configuration file; this is the code:

```
\langle load \ JSON \ configuration \ 8 \rangle \equiv
     function loadConfiguration(configurationFile)
       load parameters from JSON file
       configurationFile: Path of the configuration file
       configuration = JSON.parse(configurationFile)
       DEBUG_LEVELS = [DEBUG, INFO, WARNING, ERROR, CRITICAL]
       parallelMerge = false
       try
         if configuration["parallelMerge"] == "true"
           parallelMerge = true
           parallelMerge = false
         end
       catch
       end
       return configuration["inputDirectory"], configuration["outputDirectory"],
              configuration["bestImage"],
              configuration["nx"], configuration["ny"], configuration["nz"],
              DEBUG_LEVELS[configuration["DEBUG_LEVEL"]],
              parallelMerge
     end
Fragment referenced in 72a.
A valid JSON file has the following structure:
  "inputDirectory": "Path of the input directory",
  "outputDirectory": "Path of the output directory",
  "bestImage": "Name of the best image (with extension)",
  "nx": x grid size,
  "ny": y grid size,
  "nz": border z,
  "DEBUG_LEVEL": julia Logging level (can be a number from 1 to 5)
```

```
"parallelMerge": "true" or "false"

For example, we can write:

{
    "inputDirectory": "/home/juser/IMAGES/"
    "outputDirectory": "/home/juser/OUTPUT/",
    "bestImage": "0009.tiff",
    "nx": 2,
    "ny": 2,
    "nz": 2,
    "DEBUG_LEVEL": 2
}
```

As we can see, in a valid JSON configuration file DEBUG\_LEVEL can be a number from 1 to 5. Instead, when we explicitly define parameters, DEBUG\_LEVEL can only be one of the following Julia constants:

- DEBUG
- INFO
- WARNING
- ERROR
- CRITICAL

#### 3.3 Starting conversion

As we have already said, this module has the only responsibility to collect data input and starts other modules. These are the functions that start the process and the only exposed to the application users:

```
\langle \, Start \,\, conversion \,\, from \,\, JSON \,\, file \,\, 9 \,\rangle \equiv \\  \,\, function \,\, convertImagesToLARModel(configurationFile) \\  \,\, """ \\  \,\, Start \,\, conversion \,\, of \,\, a \,\, stack \,\, of \,\, images \,\, into \,\, a \,\, 3D \,\, model \\  \,\, loading \,\, parameters \,\, from \,\, a \,\, JSON \,\, configuration \,\, file \\  \,\, configurationFile: \,\, Path \,\, of \,\, the \,\, configuration \,\, file \\ \,\, configurationFile: \,\, Path \,\, of \,\, the \,\, configuration \,\, file \\ \,\, configurationFile: \,\, Path \,\, of \,\, the \,\, configuration \,\, file \\ \,\, configurationFile: \,\, Path \,\, of \,\, the \,\, configuration \,\, file \\ \,\, configurationFile: \,\, Path \,\, of \,\, the \,\, configuration \,\, file \\ \,\, configurationFile: \,\, Path \,\, of \,\, the \,\, configuration \,\, file \\ \,\, configurationFile: \,\, Path \,\, of \,\, the \,\, configuration \,\, file \\ \,\, configurationFile: \,\, Path \,\, of \,\, the \,\, configuration \,\, file \\ \,\, configurationFile: \,\, Path \,\, of \,\, the \,\, configuration \,\, file \\ \,\, configurationFile: \,\, Path \,\, of \,\, the \,\, configuration \,\, file \\ \,\, configurationFile: \,\, Path \,\, of \,\, the \,\, configuration \,\, file \\ \,\, configurationFile: \,\, Path \,\, of \,\, the \,\, configuration \,\, file \\ \,\, configurationFile: \,\, Path \,\, of \,\, the \,\, configuration \,\, file \\ \,\, configurationFile: \,\, ConfigurationFile: \,\, Configuration \,\, file \\ \,\, configurationFile: \,\, Configuration
```

```
inputDirectory, outputDirectory, bestImage, nx, ny, nz,
           DEBUG_LEVEL, parallelMerge = loadConfiguration(open(configurationFile))
       convertImagesToLARModel(inputDirectory, outputDirectory, bestImage,
                              nx, ny, nz, DEBUG_LEVEL, parallelMerge)
     end
     \Diamond
Fragment referenced in 72a.
\langle Start \ manual \ conversion \ 10 \rangle \equiv
     function convertImagesToLARModel(inputDirectory, outputDirectory, bestImage,
                                        nx, ny, nz, DEBUG_LEVEL = INFO, parallelMerge = false)
       Start conversion of a stack of images into a 3D model
       inputDirectory: Directory containing the stack of images
       outputDirectory: Directory containing the output
       bestImage: Image chosen for centroids computation
       nx, ny, nz: Border dimensions (Possibly the biggest power of two of images dimensions)
       DEBUG_LEVEL: Debug level for Julia logger. It can be one of the following:
         - DEBUG
         - INFO
         - WARNING
         - ERROR
         - CRITICAL
       # Create output directory
         mkpath(outputDirectory)
       catch
       end
       Logging.configure(level=DEBUG_LEVEL)
       ImagesConversion.images2LARModel(nx, ny, nz, bestImage,
                inputDirectory, outputDirectory, parallelMerge)
     end
     \Diamond
```

Fragment referenced in 72a.

## 4 PngStack2Array3dJulia

This module has the responsibility of convert a png image into an array of values that will be passed to other modules

#### 4.1 Module imports

These are modules needed for this part of the package and the public functions exported

```
⟨ modules import PngStack2Array3dJulia 11⟩ ≡
    using Images # For loading png images
    using Colors # For grayscale images
    using PyCall
    using Clustering
    using Logging
    @pyimport scipy.ndimage as ndimage

NOISE_SHAPE_DETECT=10

export calculateClusterCentroids, pngstack2array3d, getImageData, convertImages
    ⋄
```

Fragment referenced in 82a.

We need Images and Colors packages for manipulating png images and PyCall for using Python functions for clustering and filtering images. As a consequence, we need a python environment with scipy to be able to run the package

#### 4.2 Convert input to png

First thing to do in our program is getting our input folder and convert the stack of images into png format. This process lets us to avoid managing an enormous variety of formats during computation, simplifying code used for transformation.

Conversion needs the following parameters:

- inputPath: path of the folder containing the original images
- outputPath: path where we will save png images
- bestImage: name of the image chosen for centroids computing (see section 4.4)

After conversion *outputPath* will contain our png images and the function will return the new name chosen for the best image.

Now we can examine single parts of conversion process. First of all we need to specify a new name for images, keeping the right order between them; so we need to define a prefix based on number of images:

```
⟨ Define string prefix 12a⟩ ≡
   imageFiles = readdir(inputPath)
   numberOfImages = length(imageFiles)
   outputPrefix = ""
   for i in 1: length(string(numberOfImages)) - 1
      outputPrefix = string(outputPrefix, "0")
   end ◊
```

Fragment referenced in 14b.

Next we need to open the single image doing the following operations:

- 1. Open images using Images library (which relies on ImageMagick) and save them in greyscale png format
- 2. if one or both dimensions of the image are odd we need to remove one row (or column) of pixels to make it even. This will be more clear when we will introduce the grid for parallel computation (see section 5)

```
⟨ Greyscale conversion 12b⟩ ≡
    rgb_img = convert(Image{ColorTypes.RGB}, img)
    gray_img = convert(Image{ColorTypes.Gray}, rgb_img) ◊
```

Fragment referenced in 14b.

As we can see, we first need to convert image to RGB and then reconverting to greyscale. Without the RGB conversion these rows will return a stackoverflow error due to the presence of alpha channel

```
\langle Image\ resizing\ 12c \rangle \equiv
```

```
# resizing images if they do not have even dimensions
     dim = size(img)
     if(dim[1] \% 2 != 0)
       debug("Image has odd x; resizing")
       xrange = 1: dim[1] - 1
     else
       xrange = 1: dim[1]
     end
     if(dim[2] % 2 != 0)
       debug("Image has odd y; resizing")
       yrange = 1: dim[2] - 1
     else
       yrange = 1: dim[2]
     end
     img = subim(gray_img, xrange, yrange) 
Fragment referenced in 14b.
Next we just have to search for the best image and add one image if they are odd (for same
reasons we need even image dimensions)
\langle Search for best image 13a \rangle \equiv
     # Searching the best image
     if(imageFile == bestImage)
       newBestImage = string(outputPrefix[length(string(imageNumber)):end],
                                    imageNumber,".png")
     end
     imageNumber += 1 \diamond
Fragment referenced in 14b.
\langle Add \ one \ image \ 13b \rangle \equiv
     # Adding another image if they are odd
     if(numberOfImages % 2 != 0)
       debug("Odd images, adding one")
       imageWidth, imageHeight = getImageData(string(outputPath, "/", newBestImage))
```

if(imageWidth % 2 != 0)
 imageWidth -= 1

Fragment referenced in 14b.

Fianlly we have to reduce noise on the image. The better choice is using a *median filter* from package scipy.ndimage because it preserves better the edges of the image:

```
⟨ Reduce noise 14a⟩ ≡
    # Denoising
    imArray = raw(img)
    imArray = ndimage.median_filter(imArray, NOISE_SHAPE_DETECT) ◊
Fragment referenced in 14b.
```

Where imArray is an array containing all raw data from images Finally this is the code for the entire function:

```
(Convert to png 14b) =
  function convertImages(inputPath, outputPath, bestImage)
    """
  Get all images contained in inputPath directory
  saving them in outputPath directory in png format.
  If images have one of two odd dimensions, they will be resized
  and if folder contains an odd number of images another one will be
  added

inputPath: Directory containing input images
  outputPath: Temporary directory containing png images
  bestImage: Image chosen for centroids computation

Returns the new name for the best image
```

```
⟨ Define string prefix 12a⟩
  newBestImage = ""
  imageNumber = 0
  for imageFile in imageFiles
    img = imread(string(inputPath, imageFile))
    ⟨ Greyscale conversion 12b⟩
     \langle Image\ resizing\ 12c \rangle
    outputFilename = string(outputPath, outputPrefix[length(string(imageNumber)):end],
                                   imageNumber,".png")
    imwrite(img, outputFilename)
    ⟨ Search for best image 13a ⟩
    ⟨ Reduce noise 14a ⟩
    img = grayim(imArray)
    imwrite(img, outputFilename)
  end
  \langle Add \ one \ image \ 13b \rangle
  return newBestImage
end
```

Fragment referenced in 82a.

11 11 11

#### 4.3 Getting data from a png

Now we need to load information data from png images. In particular we are interested in getting width and height of an image. As stated in [W3C] document, a standard PNG file contains a *signature* followed by a sequence of *chunks* (each one with a specific type).

The signature always contain the following values:

```
137 80 78 71 13 10 26 10
```

This signature indicates that the remainder of the datastream contains a single PNG image, consisting of a series of chunks beginning with an IHDR chunk and ending with an IEND chunk. Every chunk is preceded by four bytes indicating its length.

As we are interested in width and height we need to parse the IHDR chunk. It is the first chunk in PNG datastream and its type field contains the decimal values:

```
73 72 68 82
```

The header also contains:

Width	4 bytes
Height	4 bytes
Bit depth	1 bytes
Color type	1 byte
Compression method	1 byte
Filter method	1 byte
Interlace method	1 byte

So for reading width and height we need first 24 bytes; the first eight contain the signature, then we have four bytes for length, four bytes for the type field and eight bytes for information we are interested in. This is the code:

Fragment referenced in 82a.

#### 4.4 Centroids computation

As we have seen above, this package uses greyscale images for conversion into threedimensional models and for next steps we need binary images so we can distinguish between the background and the model we want to represent. We can use clustering techniques for obtaining this result. First step is centroids calculation from a chosen image (this choice must be made from the user, because we cannot knowing in advance what is the best image for finding clusters). Moreover we compute these centroids only for an image and then reuse them when we want to cluster all other images, saving processing time.

Actually we need only two centroids, because next steps should only recognize between background and foreground pixels. This is the code used for centroid computation:

```
\langle Centroid\ computation\ 17 \rangle \equiv
     function calculateClusterCentroids(path, image, numberOfClusters = 2)
       Loads an image and calculate cluster centroids for segmentation
       path: Path of the image folder
       image: name of the image
       numberOfClusters: number of desidered clusters
       imageFilename = string(path, image)
       img = imread(imageFilename) # Open png image with Julia Package
       imArray = raw(img)
       imageWidth = size(imArray)[1]
       imageHeight = size(imArray)[2]
       # Getting pixel values and saving them with another shape
       image3d = Array(Array{Uint8,2}, 0)
       # Inserting page on another list and reshaping
       push!(image3d, imArray)
       pixel = reshape(image3d[1], (imageWidth * imageHeight), 1)
       centroids = kmeans(convert(Array{Float64}, transpose(pixel)), 2).centers
       return convert(Array{Uint8}, trunc(centroids))
     end
     \Diamond
```

Fragment referenced in 82a.

#### 4.5 Transform pixels into three-dimensional array

Now we can study the most important part of this module, where images are converted into data usable by other modules for the creation of the three-dimensional model. The basic concept consists in transforming every single pixel in an integer value representing color, and then clustering them all using centroids computed earlier. So, we can obtain a matrix containing only two values (the two centroids) representing background and foreground of the image.

Now we will follow the code. This function uses four parameters

• path: Path of the images directory

• minSlice: First image to read

• maxSlice: Last image to read

• centroids: Array containing centroids for clustering

For every image we want to transform in the interval [minSlice, maxSlice) we have to read it from disk and save pixel informations into a multidimensional Array:

```
\langle Read\ raw\ data\ 18a \rangle \equiv img = imread(imageFilename) # Open png image with Julia Package imArray = raw(img) # Putting pixel values into RAW 3d array \diamond Fragment referenced in 20.
```

The Images.jl raw function, get all pixel values saving them in an Array. In Figure 7 we can see how the array will be like for a sample greyscale image.

Finally we have to compute clusters obtaining images with only two values:

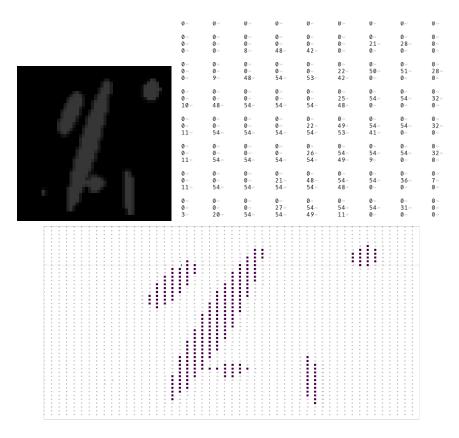

Figure 5: Reading raw data from image. (a) Original greyscale image (b) A view of raw data array (c) The entire raw data array with main color highlighted

```
index = findmin([abs(centroids[1]-centers[1]),abs(centroids[2]-centers[1])])[2]
  qnt = fill(index, size(qnt))
end

# Reshaping quantization result
  centers_idx = reshape(qnt, size(image3d[page],1), size(image3d[page],2))

# Inserting quantized values into 3d image array
  tmp = Array(Uint8, size(image3d[page],1), size(image3d[page],2))

for j in 1:size(image3d[1],2)
  for i in 1:size(image3d[1],1)
      tmp[i,j] = centroids[centers_idx[i,j]]
  end
end
```

```
image3d[page] = tmp
```

Fragment referenced in 20.

Figure 6: Image transformation. (a) Original greyscale image (b) Denoised image (c) Two-colors image

We can see that sometimes the Clustering.jl library returns the same values for both centroid centers. This could happen when the images is completely empty or it has only colored pixels. So, we need to check this cases and fill the assignments array qnt with the right values based on the centroids parameter.

This is the complete code:

```
⟨ Pixel transformation 20 ⟩ ≡

function pngstack2array3d(path, minSlice, maxSlice, centroids)

"""

Import a stack of PNG images into a 3d array

path: path of images directory
minSlice and maxSlice: number of first and last slice
centroids: centroids for image segmentation

"""

# image3d contains all images values
image3d = Array(Array{Uint8,2}, 0)

debug("maxSlice = ", maxSlice, " minSlice = ", minSlice)
files = readdir(path)

for slice in minSlice : (maxSlice - 1)
```

```
debug("slice = ", slice)
  imageFilename = string(path, files[slice + 1])
  debug("image name: ", imageFilename)
  ⟨ Read raw data 18a⟩
  debug("imArray size: ", size(imArray))

# Inserting page on another list and reshaping
  push!(image3d, imArray)

end

# Quantization
  for page in 1:length(image3d)

  ⟨ Clustering images 18b⟩

end

return image3d
end
```

Fragment referenced in 82a.

### 5 ImagesConversion

Now we will study the most important module for this package: ImagesConversion. It has the responsibility of doing the entire conversion process delegating tasks to the other modules.

#### 5.1 General algorithm

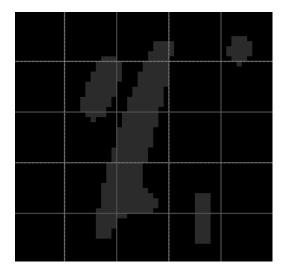

Now we will examine, in a general way, the algorithm used for conversion from a twodimensional to a three-dimensional representation of our biomedical models.

We have already seen in section 4 how to get information from a png image, obtaining arrays with only two values; one for the **background** color and one for **foreground** color. This is only the first step of the complete conversion process.

Now we focus only on a single image of the stack. Our two-dimensional representation, consists of pixels of two different colors (where only the one associated with foreground is significant); so we can obtain a three-dimensional representation simply replacing every foreground pixel with a small cube. Focusing on the entire stack of images, the full

three-dimensional representation can be obtained simply overlapping all the image representations

This algorithm is very simple, however we does not considered problems concerning lack of memory. In fact, we could have images so big that we cannot build these models entirely in memory; moreover they would require a lot of CPU time for computation. A good solution to these problems consists in taking our representation based on images and divide according to a **grid**.

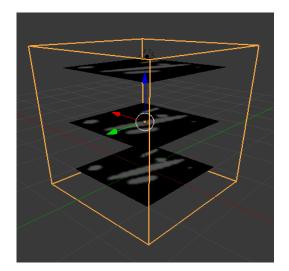

Figure 7: The grid used for parallel computation (a) 2D grid on a single image (b) 3D grid for the stack of images

So, instead of converting the entire model with a unique process, we can subdivide the input among a lot of processes, where every process will execute the conversion process on a small number of **blocks** according to the grid subdivision.

Summing up we can define the following terms, which will be used in next parts of this documentation:

- **Grid:** It is the subdivision of the entire stack of images, with sizes defined by the user. They should be powers of two (for increasing performance during border matrix computation which we will see in section 6)
- Block: It is a single cell of the grid
- **xBlock:** It is the x-coordinate of a block

• yBlock: It is the y-coordinate of a block

• **zBlock:** It is the z-coordinate of a block

xBlock and yBlock are defined on a single image, while zBlock is defined on different images; in the code it will often be replaced by terms **StartImage** and **EndImage**, which indicate the first image and the last image of that block respectively.

In next subsections we will examine the conversion algorithm in detail, showing what happens for every block of the grid.

#### 5.2 Module imports

These are modules needed for this part of the package and the public functions exported.

```
⟨ modules import ImagesConversion 23a⟩ ≡
   import GenerateBorderMatrix
   import PngStack2Array3dJulia
   import Lar2Julia
   import Model2Obj
   import LARUtils
   import Smoother

using Logging
   export images2LARModel
   ◊
```

Fragment referenced in 72b.

#### 5.3 Data preparation

As a first thing, we will see how to prepare our data for conversion process. Firstly we need to convert input images to greyscale png; so we need to create a temporary directory for saving them.

Later, we need to compute the LAR boundary operator for finding boundaries of our cells (for the generation see section 6) getting width and height from our images.

Finally we can start conversion with all these parameters calling startImageConversion function, which will be explained in next subsection.

```
\langle main function for ImagesConversion 23b \rangle \equiv
```

```
function images2LARModel(nx, ny, nz, bestImage,
                        inputDirectory, outputDirectory, parallelMerge)
 Convert a stack of images into a 3d model
 info("Starting model creation")
 numberOfClusters = 2 # Number of clusters for
                       # images segmentation
  info("Moving images into temp directory")
   mkdir(string(outputDirectory, "TEMP"))
  catch
  end
 tempDirectory = string(outputDirectory, "TEMP/")
 newBestImage = PngStack2Array3dJulia.convertImages(inputDirectory, tempDirectory,
                                                        bestImage)
  imageWidth, imageHeight = PngStack2Array3dJulia.getImageData(
                                      string(tempDirectory,newBestImage))
  imageDepth = length(readdir(tempDirectory))
 # Computing border matrix
  info("Computing border matrix")
   mkdir(string(outputDirectory, "BORDERS"))
  catch
  end
 borderFilename = GenerateBorderMatrix.getOriented3BorderPath(
                                        string(outputDirectory, "BORDERS"), nx, ny, nz)
 # Starting images conversion and border computation
  info("Starting images conversion")
 startImageConversion(tempDirectory, newBestImage, outputDirectory, borderFilename,
                       imageHeight, imageWidth, imageDepth,
                       nx, ny, nz,
                       numberOfClusters, parallelMerge)
end
```

Fragment referenced in 72b.

#### 5.4 Conversion pipeline

Now we can see how conversion of images works. In section 5.1 we have seen how to execute the single conversion of a pixel into a voxel using our grid for parallel computation. However, with that algorithm, we obtain models with internal boundaries between blocks and with squared edge. So we need to create a **conversion pipeline** which will progressively refine our models. In Figure 8 there are the steps used for our conversion

Figure 8: Images conversion pipeline

Every single step of the pipeline, is executed in parallel for every block of the grid; so we need a general purpose function for blocks iteration which will take as a parameter a function that will execute it. So we can define the iterateOnBlocks function which takes the following parameters:

- inputDirectory: Directory which contains input files for the process function
- imageHeight, imageWidth, imageDepth: Sizes of the stack of images
- imageDx, imageDy, imageDz: Sizes of the grid
- **processFunction**: Function that contains instructions for execution of a single step of the pipeline for a single block
- outputDirectory: Directory which will contains the output
- centroids: Centroids from the best image
- boundaryMat: Boundary operator for the chosen grid

This function will iterate on all blocks of the image grid executing the process function, which will be different for every pipeline step. This is the code used:

```
inputDirectory: Directory which contains input files for the process function
  imageHeight, imageWidth, imageDepth: Images sizes
  imageDx, imageDy, imageDz: Sizes of cells grid
 processFunction: Function that will be executed on a separate task on
 the entire z-Block
 outputDirectory: Directory which will contains the output
  centroidsCalc: Centroids from the best image
 boundaryMat: Boundary operator for the chosen grid
 beginImageStack = 0
 endImage = beginImageStack
 tasks = Array(RemoteRef, 0)
 for zBlock in 0:(imageDepth / imageDz - 1)
   startImage = endImage
   endImage = startImage + imageDz
   task = @spawn processFunction(inputDirectory,
                                   startImage, endImage,
                                   imageDx, imageDy,
                                   imageWidth, imageHeight,
                                   outputDirectory,
                                   centroidsCalc, boundaryMat)
   push!(tasks, task)
  end
 # Waiting for tasks
 for task in tasks
   wait(task)
  end
end <
```

Fragment referenced in 72b.

First of all we need to iterate on the grid finding the zBlock coordinate; we saw earlier that the imageDz parameter must be a divisor of the image depth, so we will have exactly imageDepth/imageDz blocks on the z coordinate. Moreover, at every zBlock correspond a startImage and an endImage where endImage - startImage = imageDz.

Now we can simply parallelize the conversion process spawning a new process for every zBlock, so we open at most imageDz images for process. Finally, we have to wait for tasks completion.

Now we can see the entire pipeline for images conversion.

First of all we need to compute the centroids from the best image using module PngStack2Array3dJulia and get the previously computed border matrix in csc sparse array format

```
\langle compute \ centroids \ and \ get \ border \ matrix \ 27a \rangle \equiv
     # Create clusters for image segmentation
     info("Computing image centroids")
     debug("Best image = ", bestImage)
     centroidsCalc = PngStack2Array3dJulia.calculateClusterCentroids(sliceDirectory,
                                                    bestImage, numberOfClusters)
     debug(string("centroids = ", centroidsCalc))
        mkdir(string(outputDirectory, "BORDERS"))
     catch
     end
     debug("Opening border file: border_", imageDx, "-", imageDy, "-", imageDz, ".json")
     boundaryMat = GenerateBorderMatrix.getBorderMatrix(
                                                   string(outputDirectory, "BORDERS/", "border_",
                                                    imageDx, "-", imageDy, "-", imageDz, ".json"))
     \Diamond
Fragment referenced in 28a.
Now we can start the pipeline:
\langle pipeline \ conversion \ 27b \rangle \equiv
     # Starting pipeline conversion
     info("Starting images conversion")
     ⟨ pixels to voxels conversion step 33 ⟩
     info("Merging boundaries")
     ⟨ boundaries merge step 36a ⟩
     info("Merging blocks")
     ⟨ block merge step 38a ⟩
     info("Smoothing models")
     \langle smoothing step 42a \rangle
     info("Merging obj models")
     ⟨ final file merge 42b ⟩
     end <
```

As we can see, last pipeline step does not require iteration on all grid blocks. This is the code for the function that starts the pipeline, with the parts explained earlier:

Fragment referenced in 72b.

#### 5.4.1 Images conversion step

Now we will focus on the first step of our pipeline conversion: *images conversion*. First thing to do is read an image calling the PngStack2Array3dJulia, after that is necessary to sort the centroid array for choosing correct background and foreground pixels.

Fragment referenced in 32.

Now we can start iterating on other blocks of the grid getting the corresponding slice of the image:

Fragment referenced in 32.

Here xStart and yStart are the absolute coordinates of the model and are calculated from the block coordinates. At the end of this process, we have an array called image with size (imageDz, imageDx, imageDy).

Now we can get the value of the single pixel into this array and, if it represents a foreground point, put it into an array called chain3D. This structure contains indexes of the linearized array created from the matrix. In Figure 9 there is a sample conversion from the matrix to the array

$$\begin{pmatrix} 0^0 & 0^2 \\ 0^1 & 0^3 \end{pmatrix} \begin{pmatrix} 46^4 & 0^6 \\ 46^5 & 46^7 \end{pmatrix} \to 0^0 \quad 0^1 \quad 0^2 \quad 0^3 \quad 46^4 \quad 46^5 \quad 0^6 \quad 46^7$$

$$\begin{pmatrix} 0^0 & 0^2 \\ 0^1 & 0^3 \end{pmatrix} \begin{pmatrix} 0^4 & 46^6 \\ 46^5 & 46^7 \end{pmatrix} \to 0^0 \quad 0^1 \quad 0^2 \quad 0^3 \quad 0^4 \quad 46^5 \quad 46^6 \quad 46^7$$

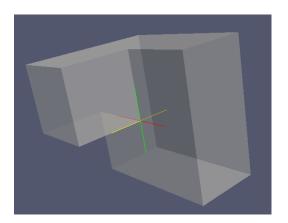

Figure 9: Transformation of a matrix resulting from a 2x2x2 grid into a linearized array (with cells indexes) (a) First example (b) Second example

As we can see from that figure, from a 2x2x2 grid we can obtain eight values for the single block (or **cell**), where the indexes for the foreground pixels represent indexes of non-empty cells in a 2x2x2 cuboidal geometry

This is the code for getting foreground pixels:

Fragment referenced in 32.

Now that we have full cells for the geometry, we can convert them into a LAR model. In particular, we are interested in cell boundaries for every block (as we want to obtain only the boundaries for the final model) so we can call function larBoundaryChain from Lar2Julia module (which will be explained in section 7). In Figure 10 there are some examples of models extracted from a single  $2 \times 2 \times 2$  block.

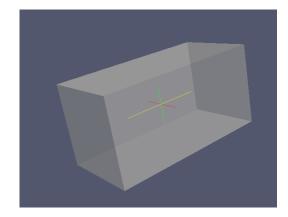

Figure 10: Sample models of 2x2x2 blocks

After model computation, next step is getting vertices and faces from model cells writing results to file. However, as we have already said, we are only interested in boundaries of

the final model while now we have only boundaries of a single block. Consequently, we have to separate boundaries from the inner faces of the block on different files (boundaries separation will be explained in section 8). As we can see later, we will merge boundaries together deleting common faces on both block borders, obtaining a model without internal faces. These are pieces of code for getting the inner block model with the boundaries and for file writing:

```
"-", yBlock, "_", startImage, "_", endImage)
     Model20bj.writeToObj(V_bottom, FV_bottom, bottom_outputFilename)
     front_outputFilename = string(outputDirectory, "MODELS/front_output_", xBlock,
                                       "-", yBlock, "_", startImage, "_", endImage)
     Model2Obj.writeToObj(V_front, FV_front, front_outputFilename)
     back_outputFilename = string(outputDirectory, "MODELS/back_output_", xBlock,
                                       "-", yBlock, "_", startImage, "_", endImage)
     Model20bj.writeToObj(V_back, FV_back, back_outputFilename)
Fragment referenced in 32.
This is the processFunction for this pipeline step
\langle image\ conversion\ process\ 32 \rangle \equiv
     function imageConversionProcess(sliceDirectory,
                                    startImage, endImage,
                                    imageDx, imageDy,
                                    imageWidth, imageHeight,
                                    outputDirectory,
                                    centroids, boundaryMat)
       Support function for converting a stack of image on a single
       independent process
       ⟨ image read and centroids sort 28b⟩
       for xBlock in 0:(imageHeight / imageDx - 1)
         for yBlock in 0:(imageWidth / imageDy - 1)
           yStart = xBlock * imageDx
           xStart = yBlock * imageDy
           xEnd = xStart + imageDx
           yEnd = yStart + imageDy
           debug("********")
           debug(string("xStart = ", xStart, " xEnd = ", xEnd))
           debug(string("yStart = ", yStart, " yEnd = ", yEnd))
           debug("theImage dimensions: ", size(theImage)[1], " ",
                            size(theImage[1])[1], " ", size(theImage[1])[2])
           ⟨ qet image slice 29 ⟩
```

```
\langle get foreground pixels 30 \rangle
             if(length(chains3D) != 0)
               # Computing boundary chain
               debug("chains3d = ", chains3D)
               debug("Computing boundary chain")
               objectBoundaryChain = Lar2Julia.larBoundaryChain(boundaryMat, chains3D)
               debug("Converting models into obj")
                 mkdir(string(outputDirectory, "MODELS"))
               catch
               end
               \langle get \ inner \ model \ and \ boundaries \ 31a \rangle
               ⟨ write block models to file 31b⟩
               debug("Model is empty")
             end
          end
        end
      end ◊
Fragment referenced in 72b.
This is the code for starting this pipeline step:
\langle pixels \ to \ voxels \ conversion \ step \ 33 \rangle \equiv
      @time iterateOnBlocks(sliceDirectory,
                           imageHeight, imageWidth, imageDepth,
                           imageDx, imageDy, imageDz,
                           imageConversionProcess, outputDirectory,
                           centroidsCalc, boundaryMat) <
Fragment referenced in 27b.
```

#### 5.4.2 Boundaries merge step

Next step of our pipeline consists in *boundaries merge*. In fact, we have already seen that for every non-empty cell we create files for the inner parts and for the boundaries of the block. So if we want a final model without boundaries between internal blocks, we need to merge them removing duplicated faces on both sides (see Section 8.6 for a better explanation of this step). The following is the processFunction:

```
\langle boundary merge process function 34 \rangle \equiv
     function mergeBoundariesProcess(modelDirectory,
                                        startImage, endImage,
                                        imageDx, imageDy,
                                        imageWidth, imageHeight,
                                        outputDirectory = None,
                                        centroidsCalc = None, boundaryMat = None)
       Helper function for mergeBoundaries.
       It is executed on different processes
       modelDirectory: Directory containing model files
       startImage: Block start image
       endImage: Block end image
       imageDx, imageDy: x and y sizes of the grid
       imageWidth, imageHeight: Width and Height of the image
       for xBlock in 0:(imageHeight / imageDx - 1)
         for yBlock in 0:(imageWidth / imageDy - 1)
           # Merging right Boundary
           firstPath = string(modelDirectory, "/right_output_", xBlock, "-", yBlock,
                              "_", startImage, "_", endImage)
           secondPath = string(modelDirectory, "/left_output_", xBlock, "-", yBlock + 1,
                              "_", startImage, "_", endImage)
           mergeBoundariesAndRemoveDuplicates(firstPath, secondPath)
           # Merging top boundary
           firstPath = string(modelDirectory, "/top_output_", xBlock, "-", yBlock,
                               "_", startImage, "_", endImage)
           secondPath = string(modelDirectory, "/bottom_output_", xBlock, "-", yBlock,
                               "_", endImage, "_", endImage + (endImage - startImage))
           {\tt mergeBoundariesAndRemoveDuplicates(firstPath, secondPath)}
           # Merging front boundary
           firstPath = string(modelDirectory, "/front_output_", xBlock, "-", yBlock,
                              "_", startImage, "_", endImage)
           secondPath = string(modelDirectory, "/back_output_", xBlock + 1, "-", yBlock,
                              "_", startImage, "_", endImage)
           mergeBoundariesAndRemoveDuplicates(firstPath, secondPath)
         end
       end
     end <
```

Fragment referenced in 72b.

For every block we do the following merges:

- right boundary with the left boundary of the next block on the right
- top boundary with the bottom boundary of the next block on the top
- front boundary with the back boundary of the next block on the front

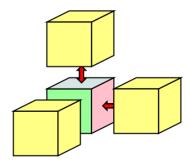

Figure 11: Merging of boundary faces. For a single block we need adjacent blocks on the right, top and front

all merges are executed by the function mergeBoundariesAndRemoveDuplicates which does the work calling the Model2Obj and LARUtils libraries for loading and cleaning of the boundaries models.

None, None) ⋄

Fragment referenced in 27b.

#### 5.4.3 Block merge step

At this step of the computation, we have files with the inner parts of a single block model and the remaining boundaries. Now we need to merge the blocks removing double vertices and faces, so we can save space and prepare our model to the *smoothing step*. This is the code of the processFunction:

```
startImage: Block start image
 endImage: Block end image
  imageDx, imageDy: x and y sizes of the grid
  imageWidth, imageHeight: Width and Height of the image
 for xBlock in 0:(imageHeight / imageDx - 1)
   for yBlock in 0:(imageWidth / imageDy - 1)
     blockCoordsV = string(xBlock, "-", yBlock, "_", startImage,
                            "_", endImage, "_vtx.stl")
     blockCoordsFV = string(xBlock, "-", yBlock, "_", startImage,
                            "_", endImage, "_faces.stl")
      arrayV = [string(modelDirectory, "/left_output_", blockCoordsV),
                string(modelDirectory, "/right_output_", blockCoordsV),
                string(modelDirectory, "/top_output_", blockCoordsV),
                string(modelDirectory, "/bottom_output_", blockCoordsV),
                string(modelDirectory, "/front_output_", blockCoordsV),
                string(modelDirectory, "/back_output_", blockCoordsV),
                string(modelDirectory, "/model_output_", blockCoordsV)]
      arrayFV = [string(modelDirectory, "/left_output_", blockCoordsFV),
                 string(modelDirectory, "/right_output_", blockCoordsFV),
                 string(modelDirectory, "/top_output_", blockCoordsFV),
                 string(modelDirectory, "/bottom_output_", blockCoordsFV),
                 string(modelDirectory, "/front_output_", blockCoordsFV),
                 string(modelDirectory, "/back_output_", blockCoordsFV),
                 string(modelDirectory, "/model_output_", blockCoordsFV)]
     V, FV = Model2Obj.getModelsFromFiles(arrayV, arrayFV)
     for i in 1:length(arrayV)
        if(isfile(arrayV[i]))
          rm(arrayV[i])
          rm(arrayFV[i])
        end
      end
     Model2Obj.writeToObj(V, FV, string(modelDirectory, "/model_output_",
                               xBlock, "-", yBlock, "_", startImage, "_", endImage))
    end
  end
end <
```

For a better explanation of the LARUtils function that remove duplicated vertices, you can see Section 8.4

This is the code for block merge starting

Fragment referenced in 27b.

#### 5.4.4 Smoothing step

Now we have obtained models without internal boundaries between blocks and without double vertices and faces in a single block. However this partial model has squared edges, so we need to smooth them. The processFunction for this step, is the following:

```
\langle Smooth \ block \ process \ function \ 38b \rangle \equiv
     function smoothBlocksProcess(modelDirectory,
                                     startImage, endImage,
                                     imageDx, imageDy,
                                     imageWidth, imageHeight,
                                     outputDirectory = None,
                                     centroidsCalc = None, boundaryMat = None)
       Smoothes a block in a single process
       modelDirectory: Path of the directory containing all blocks
                        that will be smoothed
       startImage, endImage: start and end image for this block
       imageDx, imageDy: sizes of the grid
       imageWidth, imageHeight: sizes of the images
       for xBlock in 0:(imageHeight / imageDx - 1)
         for yBlock in 0: (imageWidth / imageDy - 1)
           # Loading the current block model
           blockFileV = string(modelDirectory, "/model_output_", xBlock, "-", yBlock,
                                 "_", startImage, "_", endImage, "_vtx.stl")
           blockFileFV = string(modelDirectory, "/model_output_", xBlock, "-", yBlock,
                                 "_", startImage, "_", endImage, "_faces.stl")
```

```
# Loading only model of the current block
        blockModelV, blockModelFV = Model2Obj.getModelsFromFiles([blockFileV], [blockFileFV])
        # Loading a unique model from this block and its adjacents
        modelsFiles = Array(String, 0)
        for x in xBlock - 1:xBlock + 1
          for y in yBlock - 1:yBlock + 1
            for z in range(startImage - (endImage - startImage),(endImage - startImage), 3)
              push!(modelsFiles, string(modelDirectory, "/model_output_",
                                        x, "-", y, "_", z, "_", z + (endImage - startImage)))
            end
          end
        end
        modelsFilesV = map((s) -> string(s, "_vtx.stl"), modelsFiles)
        modelsFilesFV = map((s) -> string(s, "_faces.stl"), modelsFiles)
        modelV, modelFV = Model2Obj.getModelsFromFiles(modelsFilesV, modelsFilesFV)
        # Now I have to save indices of vertices of the current block model
        blockVerticesIndices = Array(Int, 0)
        for i in 1:length(blockModelV)
          for j in 1:length(modelV)
            if blockModelV[i] == modelV[j]
              push!(blockVerticesIndices, j)
            end
          end
          # Now I can apply smoothing on this model
          V_sm, FV_sm = Smoother.smoothModel(modelV, modelFV)
          # Now I have to get only block vertices and save them on the new model
          V_final = Array(Array{Float64}, 0)
          for i in blockVerticesIndices
            push!(V_final, V_sm[i])
          end
          outputFilename = string(modelDirectory, "/smoothed_output_", xBlock, "-",
                                  yBlock, "_", startImage, "_", endImage)
          Model2Obj.writeToObj(V_final, blockModelFV, outputFilename)
        end
     end
    end
 end
end <
```

if isfile(blockFileV)

An explanation of the smoothing algorithm used there, can be found in Section 9.2. What we need to remember here, is the importance of having the adjacent vertices for every vertex of our block. In fact, according to the chosen smoothing algorithm, every vertex is replaced with a new one with coordinates computed from the mean positions of its adjacent. However, loading of the entire model into memory cannot be done because of its sizes; so we created a simple algorithm which loads only near blocks to the current one. In fact, for every block we want to smooth, we load the twenty six adjacent blocks on all directions and the chosen one. We create a unique model with it (removing double vertices and faces) and then smoothing it with the algorithm in Smoother module. Finally we save only smoothed vertices for the chosen block and continue with the other blocks. In Figure 12 there is a graphical explanation for the algorithm.

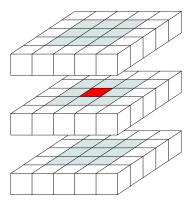

Figure 12: Smoothing of a single block. The red block at the center of the figure is the current one, while the other twenty six colored ones are the blocks that will be part of the model which will be smoothed for this iteration

Moreover, this **processFunction** can only execute a single iteration of the smoothing algorithm, so we need a function that can be able to execute more times the algorithm:

```
iterations = 1
       for i in 1:iterations
         info("Iteration ", i)
         iterateOnBlocks(modelDirectory,
                         imageHeight, imageWidth, imageDepth,
                         imageDx, imageDy, imageDz,
                         smoothBlocksProcess,
                         None, None, None)
         # Moving smoothed file for next iterations
         beginImageStack = 0
         endImage = beginImageStack
         for zBlock in 0:(imageDepth / imageDz - 1)
           startImage = endImage
           endImage = startImage + imageDz
           for xBlock in 0:(imageHeight / imageDx - 1)
             for yBlock in 0:(imageWidth / imageDy - 1)
               f_V = string(modelDirectory, "/smoothed_output_", xBlock, "-", yBlock, "_",
                            startImage, "_", endImage, "_vtx.stl")
               f_FV = string(modelDirectory, "/smoothed_output_", xBlock, "-", yBlock, "_",
                              startImage, "_", endImage, "_faces.stl")
               if(isfile(f_V))
                 if VERSION >= v"0.4"
                   mv(f_V, replace(f_V, "smoothed", "model"), remove_destination = true)
                   mv(f_FV, replace(f_FV, "smoothed", "model"), remove_destination = true)
                   mv(f_V, replace(f_V, "smoothed", "model"))
                   mv(f_FV, replace(f_FV, "smoothed", "model"))
                 end
               end
             end
           end
         end
       end
     end <
Fragment referenced in 72b.
```

We can see that after every smoothing iteration on the complete model, we need to rename the output files for the next iterations. In fact, this parallel algorithm works because for every block we do not need the current smoothed vertices for the adjacent blocks but only the old ones. However after first iteration we will have a lot of files with both the new smoothed model and the previous version; as a consequence we need to remove the old model and prepare the smoothed data for the next smoothing iteration. This is the code for starting this step:

### 5.4.5 Model creation step

At this point of the pipeline, we have a lot of files containing models for a single block; now we can merge them in a unique obj file. As we will see in Section 10, there are two different algorithms for file merging. The first one use a serial merging and it is better for traditional filesystems. The other one use a parallel algorithm which is better on a distributed filesystem. This is the code for invocation of the step:

```
⟨final file merge 42b⟩ ≡
    if parallelMerge
        @time Model2Obj.mergeObjParallel(string(outputDirectory, "MODELS"))
    else
        @time Model2Obj.mergeObj(string(outputDirectory, "MODELS")) ◊
Fragment referenced in 27b.
```

#### 6 GenerateBorderMatrix

This module has the responsibility for the generation of the border matrix operator for models boundary computation.

#### 6.1 Module imports

These are modules needed for this part of the package and the public functions exported

```
\langle modules import GenerateBorderMatrix 42c \rangle \equiv
```

```
import LARUtils
using PyCall

import JSON

export computeOriented3Border, writeBorder, getOriented3BorderPath

@pyimport sys
# Search for python modules in package folder
unshift!(PyVector(pyimport("sys")["path"]), Pkg.dir("ImagesToLARModel/src"))
@pyimport larcc # Importing larcc from local folder
```

Fragment referenced in 73a.

We can notice some lines for importing larce python library, which will be used in subsection 6.5

#### 6.2 Get border matrix from file

As we have already seen in previous sections, we need to compute boundaries for every block of the model grid. This can be done using the topological boundary operator from LAR package. However, the resulting matrix depends only on grid sizes; so it could be reused for other models. Consequently first time we need a border operator we compute it and then save it on disk for next conversions. This function does that work searching for a file containing the border and, if it does not exist, calculate and save it:

```
    function getOriented3BorderPath(borderPath, nx, ny, nz)
    """

    Try reading 3-border matrix from file. If it fails matrix
    is computed and saved on disk in JSON format

    borderPath: path of border directory
    nx, ny, nz: image dimensions
    """

    filename = string(borderPath, "/border_", nx, "-", ny, "-", nz, ".json")
    if !isfile(filename)
        border = computeOriented3Border(nx, ny, nz)
        writeBorder(border, filename)
    end
    return filename
```

end ◊

Fragment referenced in 73a.

#### 6.3 Write border matrix on file

We have already seen that for performance reasons border operator matrix is saved on file; here we will see code used for this scope. Firstly, we have defined a function writeBorder, which takes as parameters a PyObject containing a matrix (computed in subsection 6.4) and the output file path. When porting of larce library will be completed, code for conversion of python csr matrix into csc julia matrix will not be necessary.

```
⟨write Border matrix 44a⟩ ≡
function writeBorder(boundaryMatrix, outputFile)
    """
    Write 3-border matrix on json file

    boundaryMatrix: matrix to write on file
    outputFile: path of the outputFile
    """

fullBorder = pycall(boundaryMatrix["toarray"], PyAny)
    cscBorder = sparse(fullBorder)
    row = findn(cscBorder)[1]
    col = findn(cscBorder)[2]
    data = nonzeros(cscBorder)

matrixObj = MatrixObject(0, 0, row, col, data)

outfile = open(string(outputFile), "w")
    JSON.print(outfile, matrixObj)
    close(outfile)
end ◊
```

Fragment referenced in 73a.

We can see that, in final JSON file, we write an object called MatrixObject which has the following definition:

```
\langle Matrix \ object \ for \ JSON \ file \ 44b \rangle \equiv
```

```
type MatrixObject
ROWCOUNT
COLCOUNT
ROW
COL
DATA
end ◊
```

Fragment referenced in 73a.

The most important fields of this object are the last three ones; the first two contain all coordinates of the non-zero elements, the last contains all non-zero elements of the sparse matrix. So considering the full matrix V we will have that S[ROW[k], COL[k]] = V[k].

#### 6.4 Compute border matrix

Here we can see code used for computation of the border operator. As we can see, we call the python larcc module, from the LAR module, which returns a PyObject containing a sparse csr matrix. In next versions this function will be probably changed and the code for boundary computation will be moved in LAR2Julia module (also transforming all csr matrix in csc matrix) avoiding python calls.

```
⟨ compute border matrix 45⟩ ≡

# Compute the 3-border operator
function computeOriented3Border(nx, ny, nz)

"""

Compute the 3-border matrix using a modified
version of larcc
"""

V, bases = LARUtils.getBases(nx, ny, nz)
boundaryMat = larcc.signedCellularBoundary(V, bases)
return boundaryMat

end ⋄
```

Fragment referenced in 73a.

#### 6.5 Transform border matrix

Last function we will see, extracts the MatrixObject in Section 6.3 converting it into a common Julia csc sparse matrix

```
\langle transform\ border\ matrix\ in\ csc\ format\ 46a \rangle \equiv
     function getBorderMatrix(borderFilename)
       Get the border matrix from json file and convert it in
       CSC format
       11 11 11
       # Loading borderMatrix from json file
       borderData = JSON.parsefile(borderFilename)
       # Converting Any arrays into Int arrays
       row = Array(Int64, length(borderData["ROW"]))
       col = Array(Int64, length(borderData["COL"]))
       data = Array(Int64, length(borderData["DATA"]))
       for i in 1: length(borderData["ROW"])
         row[i] = borderData["ROW"][i]
       end
       for i in 1: length(borderData["COL"])
         col[i] = borderData["COL"][i]
       end
       for i in 1: length(borderData["DATA"])
         data[i] = borderData["DATA"][i]
       return sparse(row, col, data)
     end <
```

Fragment referenced in 73a.

## 7 Lar2Julia

This module contains functions used in LAR library which are converted using Julia syntax. Next versions of the software will contain more and more functions from the original LAR library (which is written in python)

#### 7.1 Module imports

These are modules used for Lar2Julia and the public functions

```
\langle modules import Lar2Julia 46b \rangle \equiv
```

```
import JSON
using Logging
export larBoundaryChain, cscChainToCellList 
Fragment referenced in 73b.
```

# 7.2 Get boundary chain from a model

Now we will observe how to compute the boundary chain of a LAR model given the list of non-empty cells and the boundary operator stored as a csc sparse matrix. This algorithm is very simply: firstly we need to convert the list of cells into a sparse array containing the LAR model. So, the resulting array (which will be called cscChain) will contain a one for every cscChain[i][1][1]  $\forall i \in \text{brcCellList}$ . Next, we just have to compute the product between the two sparse matrices and convert all values of the result into one of these:  $\{-1; +1; 0\}$  using function cscBinFilter.

```
\langle get \ boundary \ chain \ 47 \rangle \equiv
     function larBoundaryChain(cscBoundaryMat, brcCellList)
       Compute boundary chains
       # Computing boundary chains
       n = size(cscBoundaryMat)[1]
       m = size(cscBoundaryMat)[2]
       debug("Boundary matrix size: ", n, "\t", m)
       data = ones(Int64, length(brcCellList))
       i = Array(Int64, length(brcCellList))
       for k in 1:length(brcCellList)
         i[k] = brcCellList[k] + 1
       end
       j = ones(Int64, length(brcCellList))
       debug("cscChain rows length: ", length(i))
       debug("cscChain columns length: ", length(j))
       debug("cscChain data length: ", length(brcCellList))
```

```
debug("rows ", i)
 debug("columns ", j)
 debug("data ", data)
 cscChain = sparse(i, j, data, m, 1)
 cscmat = cscBoundaryMat * cscChain
 out = cscBinFilter(cscmat)
 return out
end
function cscBinFilter(CSCm)
 k = 1
 data = nonzeros(CSCm)
  sgArray = copysign(1, data)
 while k <= nnz(CSCm)
    if data[k] % 2 == 1 || data[k] % 2 == -1
      data[k] = 1 * sgArray[k]
      data[k] = 0
    end
    k += 1
  end
 return CSCm
end
```

Fragment referenced in 73b.

#### 7.3 Get oriented cells from a chain

Another operation that could be useful (even if it is not actually used in the package) consists in getting of "+1" oriented cells from a chain. For obtaining this result, it is necessary to get all non-zeros element from the sparse Julia array (remembering that if the user manually write a zero into the array it will be returned from nonzeros function anyway) and then returning only indices of cells that have a "+1" in nonzero element array.

```
⟨ get oriented cells from a chain 48⟩ ≡
   function cscChainToCellList(CSCm)
   """

Get a csc containing a chain and returns
   the cell list of the "+1" oriented faces
```

```
data = nonzeros(CSCm)
# Now I need to remove zero element (problem with Julia nonzeros)
nonzeroData = Array(Int64, 0)
for n in data
   if n != 0
      push!(nonzeroData, n)
   end
end

cellList = Array(Int64,0)
for (k, theRow) in enumerate(findn(CSCm)[1])
   if nonzeroData[k] == 1
      push!(cellList, theRow)
   end
end
return cellList
nd ◊
```

Fragment referenced in 73b.

### 7.4 Transform relationships from arrays of arrays to a sparse matrix

Another function which can be useful for our purposes is conversion between different representations of the LAR relationships. For example we often use a representation based on list of list of int but if we want to apply topological operators (such as the incident operators) we need to convert it into a matrix of values. In Figure 13 we can see an example of a LAR relationship with different representations.

```
⟨ transform relationships to csc 49⟩ ≡
function relationshipListToCSC(larRelation)
"""
Get a LAR relationship
and convert it into a CSC matrix
"""

# Build I and J arrays for creation of
# sparse matrix
data = Array(Int, 0)
I = Array(Int, 0)
J = Array(Int, 0)
for (k,row) in enumerate(larRelation)
for col in row
```

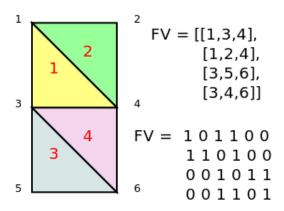

Figure 13: Different representations for faces of a simple LAR model. the first one is based on a list of list of int, while the other is a simple matrix where for every value we have  $FV[i][j] = 1 \iff face \ i \ contains \ the \ vertex \ j$ 

```
push!(I, k)
   push!(J, col)
   push!(data, 1)
   end
  end

return sparse(I, J, data)
end
```

Fragment referenced in 73b.

# 8 LARUtils

This module contains functions used for manipulation of LAR models

# 8.1 Module imports

These are modules used in LARUtils and the functions exported

```
\langle \ modules \ import \ LARUtils \ 50 \ \rangle \equiv using Logging  \\  \text{export ind, invertIndex, getBases, removeDoubleVerticesAndFaces,} \\  \text{computeModel, computeModelAndBoundaries} \\ \\
```

# 8.2 Transformation from matrix to array

First utility functions we will see, transform a matrix into an array and vice versa. We have already seen in section 5.4.1 uses of this linearized matrices; now we can focus on code for transformation.

```
⟨ conversion from matrix to array 51a⟩ ≡
function ind(x, y, z, nx, ny)

"""

Transform coordinates into linearized matrix indexes
"""

return x + (nx + 1) * (y + (ny + 1) * (z))
end ◊
```

Fragment referenced in 74a.

Here we have defined also the inverse transformation from the array to the matrix, which is useful for obtaining vertices coordinates from a cell

```
⟨ conversion from array to matrix 51b⟩ ≡
function invertIndex(nx,ny,nz)
"""
Invert indexes
"""
nx, ny, nz = nx + 1, ny + 1, nz + 1
function invertIndexO(offset)
a0, b0 = trunc(offset / nx), offset % nx
a1, b1 = trunc(a0 / ny), a0 % ny
a2, b2 = trunc(a1 / nz), a1 % nz
return b0, b1, b2
end
return invertIndexO
end ◊
```

Fragment referenced in 74a.

#### 8.3 Get bases of a LAR model

For generation of LAR models from an array of non-empty cells, we need to define a function for obtaining a base for every model, which will contain all LAR relationships:

- V: the array of vertices of a LAR model
- VV: the relationship between a vertex and itself
- EV: the relationship between an edge and its vertices
- FV: the relationship between a face and its vertices
- CV: the relationship between a cell and its vertices

From a geometrical point of view these bases create a chain composed from  $nx \times ny \times nz$  square cells (where nx ny and nz are the grid size).

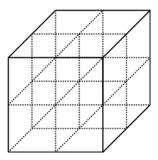

Figure 14: LAR bases geometry for a  $2 \times 2 \times 2$  grid

Now we will see in details how to obtain all LAR relationships. First of all we need to compute vertices for the geometry:

```
⟨ compute vertices 52⟩ ≡
    # Calculating vertex coordinates (nx * ny * nz)
    V = Array{Int64}[]
    for z in 0:nz
        for y in 0:ny
            for x in 0:nx
                 push!(V,[x,y,z])
            end
        end
        end
        end
```

Fragment referenced in 55a.

So we assume that our cube geometry has only integers coordinates that can vary from (0,0,0) to (nx,ny,nz)

Next we have to compute the CV relationship:

```
⟨ compute CV 53a⟩ ≡
# Building CV relationship
CV = Array{Int64}[]
for z in 0:nz-1
    for y in 0:ny-1
        for x in 0:nx-1
            push!(CV,the3Dcell([x,y,z]))
        end
    end
end
```

Fragment referenced in 55a.

For every coordinate in the space delimited by the grid size, it is called function the 3Dcell, which get the coordinate values returning a cell in the three-dimensional space:

Fragment referenced in 55a.

Now we have to compute the FV relationship, which will be widely used in this package:

```
⟨ compute FV 53c ⟩ ≡

# Building FV relationship
FV = Array{Int64}[]
v2coords = invertIndex(nx,ny,nz)

for h in 0:(length(V)-1)
x,y,z = v2coords(h)
```

```
if (x < nx) && (y < ny)
          push!(FV, [h,ind(x+1,y,z,nx,ny),ind(x,y+1,z,nx,ny),ind(x+1,y+1,z,nx,ny)])
        if (x < nx) && (z < nz)
          push!(FV, [h,ind(x+1,y,z,nx,ny),ind(x,y,z+1,nx,ny),ind(x+1,y,z+1,nx,ny)])
        end
        if (y < ny) && (z < nz)
          push! (FV, [h, ind(x,y+1,z,nx,ny), ind(x,y,z+1,nx,ny), ind(x,y+1,z+1,nx,ny)])
        end
     end <
Fragment referenced in 55a.
Finally we have the VV relationship (which is trivial)
\langle compute VV 54a \rangle \equiv
     # Building VV relationship
     VV = map((x) \rightarrow [x], 0:length(V)-1) \diamond
Fragment referenced in 55a.
and the EV relationship
\langle compute EV 54b \rangle \equiv
     # Building EV relationship
     EV = Array{Int64}[]
     for h in 0:length(V)-1
        x,y,z = v2coords(h)
        if (x < nx)
          push! (EV, [h,ind(x+1,y,z,nx,ny)])
        end
        if (y < ny)
         push!(EV, [h,ind(x,y+1,z,nx,ny)])
        end
        if (z < nz)
          push!(EV, [h,ind(x,y,z+1,nx,ny)])
        end
     end <
```

Fragment referenced in 55a.

This is the complete code for the function getBases

```
\langle get\ LAR\ bases\ 55a \rangle \equiv
function getBases(nx, ny, nz)

"""

Compute all LAR relations

"""

\langle compute\ three\ dimensional\ cells\ 53b \rangle

\langle compute\ vertices\ 52 \rangle

\langle compute\ CV\ 53a \rangle

\langle compute\ FV\ 53c \rangle

\langle compute\ VV\ 54a \rangle

\langle compute\ EV\ 54b \rangle

# return all basis
return V, (VV, EV, FV, CV)
end ⋄
```

Fragment referenced in 74a.

#### 8.4 Double vertices and faces removal

Another useful function for our models is removal of double vertices and faces. In fact, when we produce a LAR model getting only full cell from the geometry in Figure 14 we could obtain double vertices (and consequently double faces). Figure 15 shows an example of a model with these vertices:

As we can see, for every model there are a lot of double vertices, so we need to remove them for obtaining a compact representation and for next smoothing of the objects. First of all we have to identify double vertices, so it can be useful to define an order between them. Unfortunately Julia does not define a function for order array containing coordinates (which is format used in V array); so we have to define first a custom ordering function:

```
\langle vertices \ comparator \ function \ 55b \rangle \equiv
```

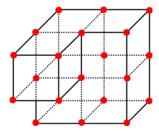

Figure 15: A sample model taken from a  $2 \times 2 \times 2$  grid with double vertices between faces in red (remember that we have only the boundaries faces for the model as we have seen in section 5.4.1)

```
function lessThanVertices(v1, v2)
    """

Utility function for comparing vertices coordinates
    """

if v1[1] == v2[1]
    if v1[2] == v2[2]
        return v1[3] < v2[3]
    end
        return v1[2] < v2[2]
    end
    return v1[1] < v2[1]
end </pre>
```

Fragment referenced in 58.

Now we can remove double vertices from the V array simply ordering them and removing all consecutive equal vertices. This procedure is more complex than a simple call to Julia unique function for removal of double elements because we need the new vertices indices for renaming faces (as we can see later)

```
⟨ removal of double vertices 56⟩ ≡
   function removeDoubleVertices(V)
    """
   Remove double vertices from a LAR model
   V: Array containing all vertices of the model
   """
   # Sort the vertices list and returns the ordered indices
```

```
orderedIndices = sortperm(V, lt = lessThanVertices, alg=MergeSort)
 orderedVerticesAndIndices = collect(zip(sort(V, lt = lessThanVertices),
                                           orderedIndices))
 newVertices = Array(Array{Float64}, 0)
 indices = zeros(Int, length(V))
 prevv = Void
 i = 1
 for (v, ind) in orderedVerticesAndIndices
    if v == prevv
      indices[ind] = i - 1
     push!(newVertices, v)
      indices[ind] = i
      i += 1
     prevv = v
    end
  end
 return newVertices, indices
end \diamond
```

Fragment referenced in 58.

As we can see the algorithm does the following steps:

- 1. Sort of vertices list
- 2. Set the current vertex index counter to 1
- 3. For every couple (vertex, index into V array) do:
  - (a) If the current *vertex* is equal to the previous one put into the indices array at position *index* the value for the current vertex index count
  - (b) If the current *vertex* is not equal to the previous one save it into a new V array, insert the indices array at position *index* the current index count and increment it by one

So at the end of this function the array new Vertices will contain all unique vertices, while the *indices* array will contain the correct index for every vertex into new Vertices and the index corresponding to the saved vertex for every deleted vertex.

Now we can use these informations for renaming all faces.

```
\langle renaming \ of \ faces \ 57 \rangle \equiv
```

```
function reindexVerticesInFaces(FV, indices, offset)
   """
   Reindex vertices indices in faces array

FV: Faces array of the LAR model
   indices: new Indices for faces
   offset: offset for faces indices
   """

for f in FV
   for i in 1: length(f)
      f[i] = indices[f[i] - offset] + offset
   end
   end
   return FV
end
```

Fragment referenced in 58.

Here we can observe a *offset* parameter, which is necessary only if we are renaming faces whose indices doesn't start from zero; actually in ImagesToLARModel it is always equal to zero.

Finally for removing double faces, we only have to call unique function on renamed faces. This is the final code

```
⟨removal of double vertices and faces 58⟩ ≡
   ⟨vertices comparator function 55b⟩

function removeDoubleVerticesAndFaces(V, FV, facesOffset)

"""

Removes double vertices and faces from a LAR model

V: Array containing all vertices
FV: Array containing all faces
facesOffset: offset for faces indices

"""

newV, indices = removeDoubleVertices(V)
reindexedFaces = reindexVerticesInFaces(FV, indices, facesOffset)
newFV = unique(FV)

return newV, newFV
```

```
end \langle removal of double vertices 56\rangle \langle renaming of faces 57\rangle \diamond Fragment referenced in 74a.
```

#### 8.5 Creation of a LAR model

Now we can see code used for creation of a LAR model given the sparse array containing full cells of our block (**objectBoundaryChain** as we had seen in Section 7.2). We also need the following parameters:

- imageDx, imageDy, imageDz: The grid size
- xStart, yStart, zStart: The coordinate offsets for the current block vertices
- facesOffset: The offset for faces of this block

First thing to do is define models that will be returned from the function:

```
\langle models definition 59 \rangle =
V_model = Array(Array{Int}, 0)
FV_model = Array(Array{Int}, 0)

V_left = Array(Array{Int}, 0)
FV_left = Array(Array{Int}, 0)

V_right = Array(Array{Int}, 0)
FV_right = Array(Array{Int}, 0)

V_top = Array(Array{Int}, 0)
FV_top = Array(Array{Int}, 0)

V_bottom = Array(Array{Int}, 0)

FV_bottom = Array(Array{Int}, 0)

V_front = Array(Array{Int}, 0)

V_front = Array(Array{Int}, 0)

FV_front = Array(Array{Int}, 0)

V_back = Array(Array{Int}, 0)

FV_back = Array(Array{Int}, 0)
```

We can see from Figure 16 that our grid is divided into seven parts.

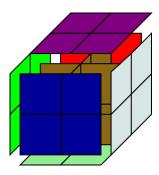

Figure 16: Decomposition of a LAR model into seven parts: the inside model (brown), the left boundary (green), the right boundary (light blue), the top boundary (purple), the bottom boundary (light green), the front boundary (blue), the back boundary (red)

We need this decomposition because we are interested in boundaries of the entire model, while we currently have boundaries only for blocks. So we need to split the inner parts of a single block model, as we need to freely merge boundaries between adjacent blocks removing the common faces. Function for boundaries merging are shown in subsection 8.6.

After model definition we have to get the cells indices from the block boundary chain and for every non-empty cell we have found, choose the correct model for it. We can observe that every boundary face has a fixed coordinate; for example all faces on the top boundary have the maximum z-coordinate, or faces on right boundary have the maximum y-coordinate (as shown in Figure 17)

So we can define a series of functions for checking the membership of a given face to a boundary exploiting these fixed coordinates:

```
\begin{tabular}{ll} $\langle$ check membership of a face to a boundary $60$ $\rangle$ $\equiv$ & function isOnLeft(face, V, nx, ny, nz) $$ $"""$ & Check if face is on left boundary $$"""$ & for(vtx in face) $$ & if(V[vtx + 1][2] != 0) $$ & return false $$ & end $$ \end $$
```

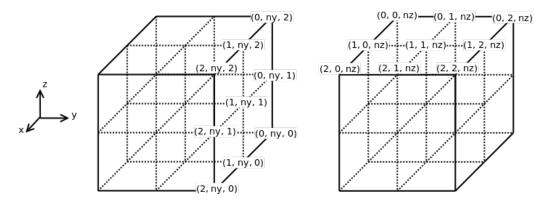

Figure 17: Boundaries coordinates for top and right boundaries of a  $2 \times 2 \times 2$  grid. We can observe that every boundary has a fixed coordinate

```
end
  return true
end
function isOnRight(face, V, nx, ny, nz)
  Check if face is on right boundary
  for(vtx in face)
    if(V[vtx + 1][2] != ny)
      return false
    end
  end
  return true
end
function isOnTop(face, V, nx, ny, nz)
  Check if face is on top boundary
  for(vtx in face)
    if(V[vtx + 1][3] != nz)
      return false
    end
  end
```

```
return true
end
function isOnBottom(face, V, nx, ny, nz)
  Check if face is on bottom boundary
  for(vtx in face)
    if(V[vtx + 1][3] != 0)
      return false
    end
  end
  return true
end
function isOnFront(face, V, nx, ny, nz)
  Check if face is on front boundary
  for(vtx in face)
    if(V[vtx + 1][1] != nx)
      return false
    end
  end
  return true
end
function isOnBack(face, V, nx, ny, nz)
  Check if face is on back boundary
  for(vtx in face)
    if(V[vtx + 1][1] != 0)
      return false
    end
  end
  return true
end \diamond
```

Fragment referenced in 64.

After choosing of the right model, we have to insert our face into it. We can do it with the following function, which takes vertices and faces of the base and the model, the face, and the offset of the current face for the model chosen:

```
\langle add \ a \ face \ to \ a \ model \ 63 \rangle \equiv
     function addFaceToModel(V_base, FV_base, V, FV, face, vertex_count)
       Insert a face into a LAR model
       V_base, FV_base: LAR model of the base
       V, FV: LAR model
       face: Face that will be added to the model
       vertex_count: Indices for faces vertices
       new_vertex_count = vertex_count
       for vtx in FV_base[face]
         push!(V, [convert(Int, V_base[vtx + 1][1] + xStart),
                           convert(Int, V_base[vtx + 1][2] + yStart),
                          convert(Int, V_base[vtx + 1][3] + zStart)])
         new_vertex_count += 1
       end
       push!(FV, [vertex_count, vertex_count + 1, vertex_count + 3])
       push!(FV, [vertex_count, vertex_count + 3, vertex_count + 2])
       return new_vertex_count
     end <
```

Fragment referenced in 64.

As we can see, for every face we put into the model FV array two faces, in fact our final representation is not based on square faces but on triangular faces.

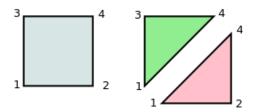

Figure 18: Triangulation of a single face

This is the complete code for creation of a model

```
\langle LAR \ model \ creation \ 64 \rangle \equiv
     ⟨ check membership of a face to a boundary 60 ⟩
     function computeModelAndBoundaries(imageDx, imageDy, imageDz,
                             xStart, yStart, zStart,
                             objectBoundaryChain)
       11 11 11
       Takes the boundary chain of a part of the entire model
       and returns a LAR model splitting the boundaries
       imageDx, imageDy, imageDz: Boundary dimensions
       xStart, yStart, zStart: Offset of this part of the model
       objectBoundaryChain: Sparse csc matrix containing the cells
       \langle add \ a \ face \ to \ a \ model \ 63 \rangle

# 8.6 Removing double faces and vertices from boundaries

In previous section, we have seen how to create a LAR model from the chain list. However this model contains all borders between blocks, while we are only interested in borders for the entire image. So, we will see functions for boundaries merging with removal of double faces and vertices from both sides.

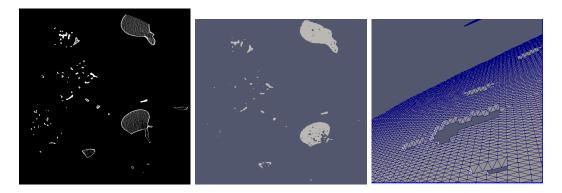

Figure 19: Creation of a sample model. (a) The original image (b) The three-dimensional model (c) The three-dimensional model (detail with triangular faces)

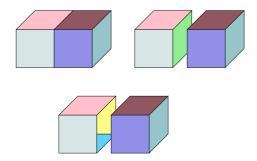

Figure 20: Removal of double faces from boundaries. (a) Two adjacent blocks (b) The same blocks exploded on x axis (c) Result of the removal on the exploded blocks

The algorithm for the removal is very simply. First of all we need to remove double vertices from models in the usual way using removeDoubleVertices function and re-indexing all faces. Next we count all elements in re-indexed faces array removing elements with more than one occurrence and create an array of faces with an explicit representation of vertices ( $FV_{-}vertices$ ). Now we can safely remove double vertices on the other side of the boundary without losing the correct indexing in the faces. Finally we can create the final faces array with only remaining vertices comparing coordinates in  $FV_{-}vertices$  with the ones in the last vertices array.

Code for this function is the following:

```
\langle Removal of double vertices and faces from boundaries 66 \rangle \equiv function removeVerticesAndFacesFromBoundaries(V, FV) """ Remove vertices and faces duplicates on boundaries models
```

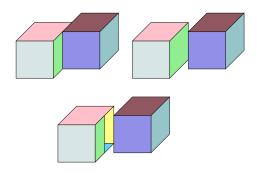

Figure 21: Same as Figure 20 with another model

```
V,FV: lar model of two merged boundaries
newV, indices = removeDoubleVertices(V)
uniqueIndices = unique(indices)
# Removing double faces on both boundaries
FV_reindexed = reindexVerticesInFaces(FV, indices, 0)
FV_unique = unique(FV_reindexed)
FV_cleaned = Array(Array{Int}, 0)
for f in FV_unique
  if(count((x) \rightarrow x == f, FV\_reindexed) == 1)
    push!(FV_cleaned, f)
  end
end
# Creating an array of faces with explicit vertices
FV_vertices = Array(Array{Array{Float64}}, 0)
for i in 1 : length(FV_cleaned)
  push!(FV_vertices, Array(Array{Float64}, 0))
  for vtx in FV_cleaned[i]
   push!(FV_vertices[i], newV[vtx])
  end
end
V_final = Array(Array{Float64}, 0)
FV_final = Array(Array{Int}, 0)
# Saving only used vertices
for face in FV_vertices
  for vtx in face
```

```
push!(V_final, vtx)
end
end

V_final = unique(V_final)

# Renumbering FV
for face in FV_vertices
  tmp = Array(Int, 0)
  for vtx in face
    ind = findfirst(V_final, vtx)
    push!(tmp, ind)
  end
  push!(FV_final, tmp)
end

return V_final, FV_final
```

# 9 Smoother

This module contains functions used for smoothing LAR models

## 9.1 Get adjacent vertices

As we will see in next subsection, for executing a smoothing algorithm we need to know adjacent vertices to a given one. So we need a VV relationship, where for every vertex index i, we have a list of adjacent vertices.

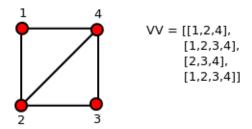

Figure 22: VV relationship for a simple model

Algorithm is very simple and exploit the following property: for triangular faces all vertices are linked together. So we just need to search for every vertex i all faces that contain it and add all their vertices to a list. VV will contain a concatenation of all these lists

```
\langle get \ adjacent \ vertices \ 69 \rangle \equiv
     function adjVerts(V, FV)
        Compute the adjacency graph of vertices
        of a LAR model
        V, FV: LAR model
        Returns the list of indices of vertices adjacent
        to a vertex
        11 11 11
        VV = Array{Int}[]
        for i in 1:length(V)
          row = Array(Int, 0)
          for face in FV
            if i in face
              for v in face
                 push!(row, v)
               end
            end
          end
          if length(row) == 0
            push!(row, i)
          push!(VV, collect(unique(row)))
        end
        return VV
     end \diamond
```

Fragment referenced in 82b.

## 9.2 Laplacian smoothing

There are many different algorithms for mesh smoothing. The simpler and the one we used in this library is **laplacian smoothing**. For each vertex in a mesh, a new position is chosen according to local information (such as the coordinates of neighbors) and the vertex is moved there. If that mesh is topologically a rectangular grid (so each internal vertex is connected to four neighbors) then this operation produces the *Laplacian* of the mesh.

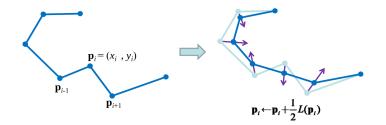

Figure 23: Laplacian smoothing (picture taken from the *Geometry Processing Algorithms* course at Stanford University)

As we can see from Figure 23, with substitution of every vertex position with the mean of the neighbors positions, we can obtain a curve with smoothed edges. This procedure can be repeated many times, so we can obtain a smoother model. For example, in Figure 25, we can see this algorithm applied on a sample mesh with three iterations.

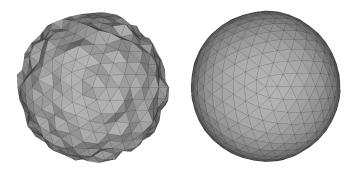

Figure 24: Laplacian smoothing for a sample mesh. (a) Original mesh (b) Mesh after three iterations of the smoothing algorithm (picture taken from a *Digital Geometry Processing* course at IMPA)

This is the code for the smoothing function; it takes a single LAR model and returns the smoothed model.

```
⟨laplacian smoothing 70⟩ =
function smoothModel(V, FV)
"""

Execute a Laplacian smoothing on a LAR model returning
the new smoothed model

V, FV: LAR model
"""
```

```
VV = adjVerts(V, FV)
  newV = Array(Array{Float64},0)
  V_temp = Array(Array{Float64},0)
  for i in 1:length(VV)
    adjs = VV[i]
    # Get all coordinates for adjacent vertices
    coords = Array(Array{Float64}, 0)
    for v in adjs
      push!(coords, V[v])
    end
    # Computing sum of all vectors
    sum = [0.0, 0.0, 0.0]
    for v in coords
      sum += v
    end
    # Computing convex combination of vertices
    push!(newV, sum/length(adjs))
  end
  return newV, FV
end \diamond
```

function mergeObjProcesses(fileArray, facesOffset = Nothing)
 Merge files on a single process
 fileArray: Array containing files that will be merged
 facesOffset (optional): if merging faces files, this array contains
   offsets for every file
  11 11 11
  if(contains(fileArray[1], string("_vtx.stl")))
   # Merging vertices files
   offsets = Array(Int, 0)
   push!(offsets, countlines(fileArray[1]))
   vertices_count = mergeVerticesFiles(fileArray[1], fileArray[2], countlines(fileArray[1]))
   rm(fileArray[2]) # Removing merged file
   push!(offsets, vertices_count)
   for i in 3: length(fileArray)
      vertices_count = mergeVerticesFiles(fileArray[1], fileArray[i], vertices_count)
      rm(fileArray[i]) # Removing merged file
```

```
push!(offsets, vertices_count)
   end
   return offsets
  else
   # Merging faces files
   mergeFacesFiles(fileArray[1], fileArray[2], facesOffset[1])
   rm(fileArray[2]) # Removing merged file
   for i in 3 : length(fileArray)
     mergeFacesFiles(fileArray[1], fileArray[i], facesOffset[i - 1])
     rm(fileArray[i]) # Removing merged file
   end
  end
end
function mergeObjHelper(vertices_files, faces_files)
 Support function for mergeObj. It takes vertices and faces files
 and execute a single merging step
 vertices_files: Array containing vertices files
 faces_files: Array containing faces files
 numberOfImages = length(vertices_files)
 taskArray = Array(Int, 0)
  assignTasks(1, numberOfImages, taskArray)
 # Now taskArray contains first files to merge
 numberOfVertices = Array(Int, 0)
 tasks = Array(RemoteRef, 0)
 for i in 1 : length(taskArray) - 1
   task = @spawn mergeObjProcesses(vertices_files[taskArray[i] : (taskArray[i + 1] - 1)])
   push!(tasks, task)
   #append!(numberOfVertices, mergeObjProcesses(vertices_files[taskArray[i] : (taskArray[i +
  end
 # Merging last vertices files
 task = @spawn mergeObjProcesses(vertices_files[taskArray[length(taskArray)] : end])
 push!(tasks, task)
 #append!(numberOfVertices, mergeObjProcesses(vertices_files[taskArray[length(taskArray)] : e.
 for task in tasks
   append!(numberOfVertices, fetch(task))
  end
 debug("NumberOfVertices = ", numberOfVertices)
```

```
# Merging faces files
 tasks = Array(RemoteRef, 0)
 for i in 1 : length(taskArray) - 1
   task = @spawn mergeObjProcesses(faces_files[taskArray[i] : (taskArray[i + 1] - 1)],
                                    numberOfVertices[taskArray[i] : (taskArray[i + 1] - 1)])
   push!(tasks, task)
   #mergeObjProcesses(faces_files[taskArray[i] : (taskArray[i + 1] - 1)],

  task = @spawn mergeObjProcesses(faces_files[taskArray[length(taskArray)] : end],
                                  numberOfVertices[taskArray[length(taskArray)] : end])
 push!(tasks, task)
  #mergeObjProcesses(faces_files[taskArray[length(taskArray)] : end],
                       numberOfVertices[taskArray[length(taskArray)] : end])
 for task in tasks
   wait(task)
 end
end
function mergeObjParallel(modelDirectory)
 Merge stl files in a single obj file using a parallel
  approach. Files will be recursively merged two by two
 generating a tree where number of processes for every
  step is maximized
 Actually use of this function is discouraged. In fact
  speedup is influenced by disk speed. It could work on
 particular systems with parallel accesses on disks
 modelDirectory: directory containing models
 files = readdir(modelDirectory)
 # Appending directory path to every file
 files = map((s) -> string(modelDirectory, "/", s), files)
 # While we have more than one vtx file and one faces file
```

```
while(length(files) != 2)
   vertices_files = files[find(s -> contains(s,string("_vtx.stl")), files)]
   faces_files = files[find(s -> contains(s,string("_faces.stl")), files)]
   # Merging files
   mergeObjHelper(vertices_files, faces_files)
   files = readdir(modelDirectory)
   files = map((s) -> string(modelDirectory, "/", s), files)
  end
 mergeVerticesFiles(files[2], files[1], 0)
 mv(files[2], string(modelDirectory, "/model.obj"))
 rm(files[1])
end
function getModelsFromFiles(arrayV, arrayFV)
 Get a LAR models for two arrays of vertices
 and faces files
 arrayV: Array containing all vertices files
 arrayFV: Array containing all faces files
 V = Array(Array{Float64}, 0)
 FV = Array(Array{Int}, 0)
 offset = 0
